## OUTLINE/TABLE OF CONTENTS

---

- **Cliff-Ramp Structures: 031122 (EMERALD 2):**
  - Flight paths, orientation and general conditions [slides 3-9](#)
  - High pass filtered signals [slides 10-12](#)
  - Band pass filtered signals and correlations [slides 13-16](#)
  - Structure function and billow height estimate [slide 17-18](#)
- **Cliff-Ramp Structures: 040922 during climb segment:**
  - Flight paths, orientation and general conditions [slides 19-24](#)
  - High pass filtered signals [slides 25-27](#)
  - Band pass filtered signals and correlations [slides 28-31](#)
  - Structure function and billow height estimate [slide 32-34](#)
- **Comparison of 031122 and 040922 with DNS and other CR cases**
  - Aspect ratio Wave features [slides 35-36](#)
  - Turbulence scaling [slides 37-38](#)
  - Length scale and layer “age” [slides 39-42](#)
  - Scaling with turbulent Reynolds numbers [slide 43](#)
- **Summary [slide 44](#)**

## CLIFF RAMPS: 9.7 km SEGMENT ON 031122 (EMERALD 2)

- Segment is across and below outflow of thunderstorm.
- CR's seen near middle of segment
- Vertical gradients estimated during climb out at end of segment

# RAW PROFILES

- Low pass filtered data (dashed lines)
  - 4<sup>th</sup> order Butterworth filter, with 8.25 km cutoff wavelength)
  - Use to de-trend signals to better analyze CR behavior (free of low frequency variations).

- Filtered data reveal wavelike pattern in temperature and in zonal and meridional velocities, especially around cliff ramps (30-40 km)
  - Wave features also present in vertical velocity, but these are not seen in plot due to vertical scale.

## RAW PROFILES: CLOSEUP ON CLIFF RAMP REGION

- Close-up better highlights both CR structures in temperature and wavelike features in temperature and velocity.

- Wave has wavelength of about 12 km.

- Temperature and velocities appear to be 180 degrees out of phase.

- CRs appear near peak in temperature wave.

- Wind speeds are small– less than 3.5 m/s.

- Explore two zones with possible CRs **I** and **II**

## HIGH PASS FILTERED POTENTIAL TEMPERATURE: I

- 5 distinct cliffs, though last one looks weaker than others
- Pattern is very regular
- Are these CRs or RCs?
  - First cliff seems to be preceded by ramp, but last cliff is also followed by a ramp.
- Third order structure function confirms cliffs
  - Also confirms cliff 5 is weaker than others.

## HIGH PASS FILTERED POTENTIAL TEMPERATURE II

- Closeup of Zone II does not reveal distinct CR patterns, though some structures are evident with approximately the same wavelength as the CRs in Zone I.

- Third order structure function confirms that structures are weaker than cliffs in Zone I (same y axis scale as previous slide) and reveals that they are symmetric.

- Are these KH either before or after cliffs form (degraded cliffs?)

# CLIMBOUT DATA AND GRADIENT ESTIMATES

- Gradients found by fitting data at beginning of climb-out from 9.7 km.

- **Meridional, zonal and horizontal (in mean wind direction)** velocities all display negative vertical gradients

- Relatively strong gradients considering the weak winds.

- Some uncertainty associated with choosing appropriate range for curve fit.

- Ri number estimate

- $S_z = 0.0123 \text{ s}^{-1}$

- $N_z = 0.0084 \text{ s}^{-1}$

- $Ri = 0.47$

## DIRECTIONS AND FLIGHT PATHS

- In proximity to CRs (boxed sketches)
  - Along-wind component of flight path is against wind
  - 35 to 50 degree difference between wind flight directions.
- During climb-out from 9.7 km
  - Flight and wind directions are nearly perpendicular
  - Shear and wind directions are almost along same line
    - Opposite directions consistent with negative shear
- Large difference between wind directions near CRs and during climb raises doubts about relevance of the gradients estimated during climb to the behavior of CRs

## CR DIMENSIONS

- Wavelengths: in flight direction (and wind direction)

- CR 1: 800 m (642 m)
- CR 2: 708 m (548 m)
- CR 3: 806 m (604 m)
- CR 4: 777 m (544 m)
- CR 5: 600 m (375 m)

- Why do we see CRs if shear is negative?
  - Would expect to see RC like 000606.

## HIGH PASS FILTERED POTENTIAL TEMPERATURE

---

- Zonal velocity decrease coincident with temperature cliffs
- Consistent with negative vertical shear

- Meridional velocity decrease coincident with temperature cliffs
- Also consistent with negative vertical shear

## HIGH PASS FILTERED POTENTIAL TEMPERATURE

---

- Horizontal velocity sometimes increases at cliff and sometimes decreases.

- Would expect decrease if shear is negative

- Vertical velocity fluctuations increase near cliffs

- Some large scale pattern seen, though correlation with temperature unclear.

## BAND-PASS FILTERED TEMP. AND HORIZ. VELOCITY

- Overall positive correlation evident, but inconsistent during cliffs.

- Positive correlation for cliffs 1, 3 and 4, negative for 5, uncertain for 2.

- Correlation coefficient relatively low compared to CRs from other flights

$$C_{Q^*U^*} = 0.43$$

- Heat flux echoes lack of consistent correlation

## BAND-PASS FILTERED TEMP. AND ZONAL VELOCITY

Non-dim. filtered  $\theta$  and  $U_z$  : 031122 9.7 km

- Mostly negative correlation.
- Higher correlation coefficient than for horizontal velocity.

$$C_{\theta^* U_z^*} = -0.73$$

Non-dim. filtered Horiz. Heat Flux : 031122 9.7 km

- Heat flux almost entirely negative, with two bursts near cliffs 3 and 4.

## BAND-PASS FILTERED TEMP. AND MERID. VELOCITY

Non-dim. filtered  $\theta$  and  $U_M$ : 031122 9.7 km

- Mostly negative correlation.
- Higher correlation coefficient than for horizontal velocity, though smaller than zonal velocity.

Non-dim. filtered Horiz. Heat Flux : 031122 9.7 km

$$C_{Q^*U_M^*} = -0.62$$

- Heat flux almost entirely negative— don't see two bursts near cliffs 3 and 4 that were seen in zonal heat flux.

## BAND-PASS FILTERED TEMP. AND VERTICAL VELOCITY

- $W$  seems to be 180 degree out of phase with  $q$  near cliffs, with decreasing  $W$  during cliffs (4<sup>th</sup> cliff is exception)
- Correlation coefficient about the same as for CRs seen in other flights

$$C_{Q*W*} = -0.22$$

- Vertical heat flux shows both negative and positive bursts near cliffs.

# STRUCTURE FUNCTIONS & CONSTANTS

- Near CRs (top plot)

$$C_T^2 = 0.000511$$

$$C_U^2 = 0.00445 = 8.7 C_T^2$$

$$C_V^2 = 0.00501 = 1.14 C_U^2$$

$$C_W^2 = 0.00393 = 0.88 C_U^2$$

- For entire 9.7 km segment (bottom plot)

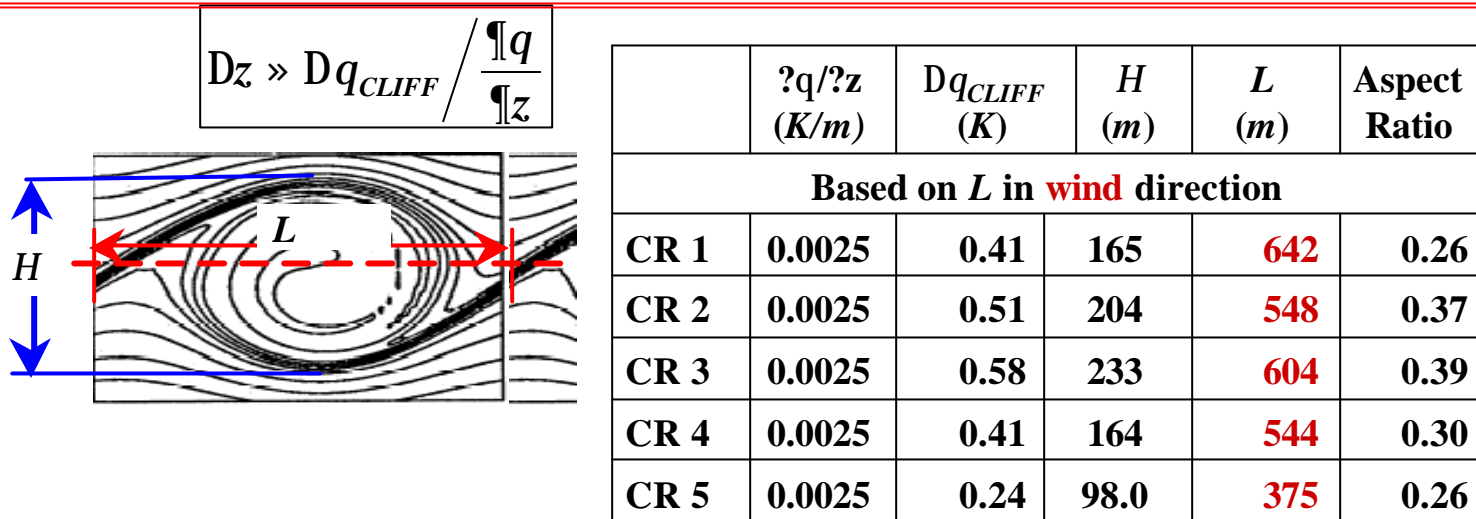

$$C_T^2 = 0.000151$$

$$C_U^2 = 0.0011 = 6.8 C_T^2$$

$$C_V^2 \sim C_W^2 \sim C_U^2$$

- Values lower than those near CRs
- $D_{TT}$  exhibits slope of 1 below 100 m (dashed line)

## BILLOW HEIGHT AND ASPECT RATIO: 031122

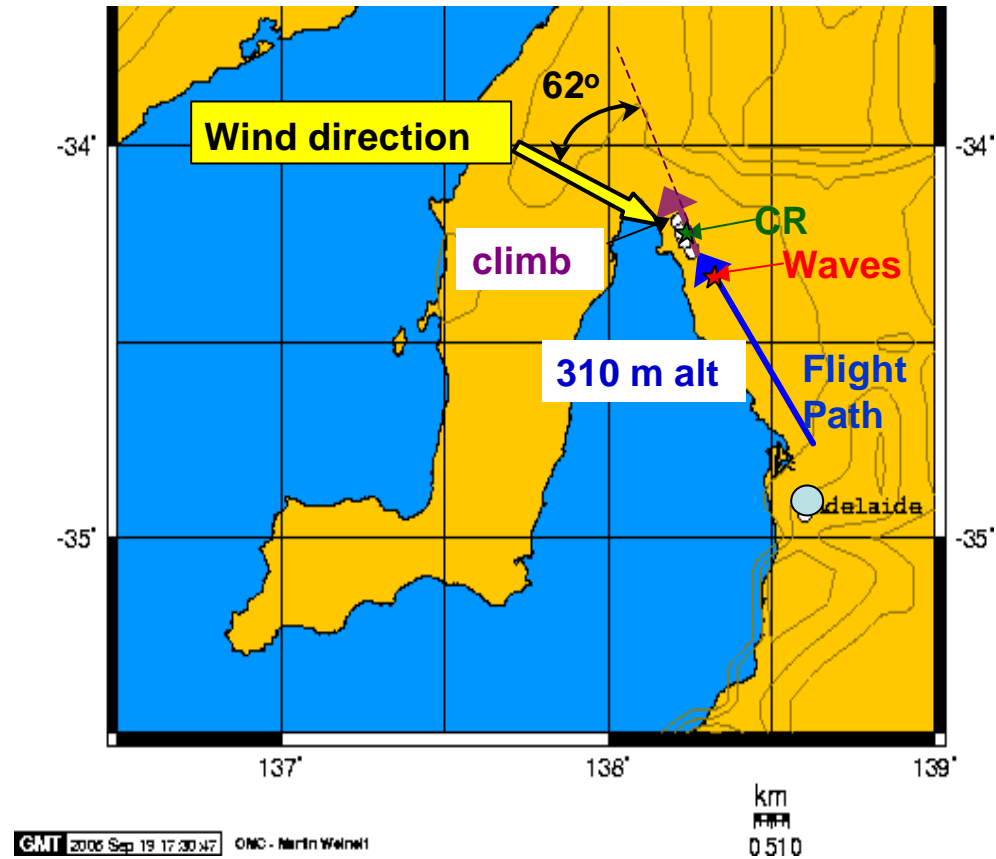

- Billow height ranges from 98 to 233 meters, resulting in aspect ratios of 0.26 to 0.39.
  - Last cliff is weak– exclude from averages
    - Average height = 191 m
  - Aspect ratios are similar to those found for CRs for other flights. See slide.

## CLIFF RAMPS: CLIMB IN BOUNDARY LAYER ON 040922

- 310 m level featured very distinct waves (see Briefing 2)
- Cliff ramps seen during climb out segment following 310 m segment.

### Flight Paths

# CLIMB PROFILES

- Low pass filtered data (dashed lines)
  - 4<sup>th</sup> order Butterworth filter, with 0.01 Hz cutoff frequency (approx. 4.1 km horizontal distance or 350 m vertical distance)
  - Use to de-trend signals to better see CR behavior
  - Calculate vertical gradients.
- Zonal velocity is increasing (+ shear) but meridional velocity is decreasing (- shear)
- How does this affect CR versus RC?

# HIGH PASS FILTERED POTENTIAL TEMPERATURE

- High pass filtered using same cutoff frequency as low pass filtering (slide 2)

- CR structures clearly evident in detrended signal between 500 and 780 meter altitudes

- 2 distinct cliffs.

- Moderate turbulence

- 250 meters high?

- Use gradients from low pass filter data to calculate Ri nos.

- Ri well above 0.25 during waves

- Ri decreases below 0.25 just before 1<sup>st</sup> cliff and after 2<sup>nd</sup> cliff

## LOW PASS FILTERED GRADIENTS AND RI NOS.

- Richardson number shows “hump” between first and second cliff
- Increasing Ri after first cliff is due to decreasing shear ( $S_z$ ) relative Buoyancy frequency ( $N_z$ ) due mainly to decreasing Zonal shear.

- Decreasing Ri before second cliff due to increasing (magnitude) of meridional shear.

## LOW PASS FILTERED DIRECTIONS

- Significant changes from first cliff to end of second ramp (around 750 m).
  - Wind direction changes 22°
  - Shear direction changes 71°.
  - This is due to increasing magnitude of meridional velocity and shear (see slides 2 and 4)
- Direction of wind and AC heading differ by an average of 62 degrees.
- Climb gradient increases from 0.05 (20:1) to 0.10 (10:1) during first CR

## ORIENTATIONS

### Before CRs

$$Dg_{AC\_WIND} = 43^\circ$$

$$Dg_{AC\_SHEAR} = 77^\circ$$

### Cliff 1

$$Dg_{AC\_WIND} = 66^\circ$$

$$Dg_{AC\_SHEAR} = 67^\circ$$

### Cliff 2

$$Dg_{AC\_WIND} = 62^\circ$$

$$Dg_{AC\_SHEAR} = 1^\circ$$

### After CRs

$$Dg_{AC\_WIND} = 43^\circ$$

$$Dg_{AC\_SHEAR} = 2^\circ$$

- This shows significant changes in shear direction during CRs
- Difference between wind and shear direction is about the same before and after CRs (43 degrees) and is about the same for the two cliffs (62-66 degrees)
- How are cliffs oriented? Only one probe, so can't determine from data

## HIGH PASS FILTERED POTENTIAL TEMPERATURE

- Detrended data is plotted versus horizontal distance traveled.
- Wavelength in flight direction
  - CR 1: 1.82 km
  - CR 2 1.34 km
- If CRs are oriented in wind direction, then wavelengths are
  - CR 1: 740 m
  - CR 2 630 m
- Third order structure function confirms cliffs.

## HIGH PASS FILTERED POTENTIAL TEMPERATURE

- Zonal velocity increase coincident with temperature cliffs

- Meridional velocity decrease coincident with temperature cliffs
- Consistent with negative vertical shear

# HIGH PASS FILTERED POTENTIAL TEMPERATURE

---

- Vertical velocity fluctuations increase near cliffs
- Also show large scale pattern, though correlation with temperature unclear.
- Possible wave just before cliff?
- Horizontal velocity is velocity in mean wind direction (direction found from low pass filtered data).
- Essentially the same as zonal velocity for first CR, but includes contribution from meridional velocity during 2<sup>nd</sup> CR.

## BAND-PASS FILTERED TEMP. AND HORIZ. VELOCITY

- Seems well correlated, though correlation coefficient is not as high as CR from other flights

$$C_{\theta^*U^*} = 0.48$$

- Lower correlation coeff. could be due to phase shift around 2<sup>nd</sup> cliff.

- Heat flux dominated by cliff

## BAND-PASS FILTERED TEMP. AND ZONAL VELOCITY

Non-dim. filtered  $\theta$  and  $U_z$ : 040922 climb CR

- Behavior nearly the same as horizontal velocity (previous slide).

$$C_{Q*U_z^*} = 0.50$$

Non-dim. filtered Horiz. Heat Flux : 040922 climb CR

## BAND-PASS FILTERED TEMP. AND MERID. VELOCITY

Non-dim. filtered  $Q$  and  $U_M$ : 040922 climb CR

- Higher correlation coefficient than zonal or horiz.

$$C_{Q*U_M*} = -0.66$$

- Negative value consistent with negative vertical shear of  $U_M$

Non-dim. filtered Horiz. Heat Flux : 040922 climb CR

- Heat flux negative and dominated by cliff response

## BAND-PASS FILTERED TEMP. AND VERTICAL VELOCITY

- Correlation between  $W$  and  $q$  is stronger than CR's from other flights, but its not consistent for the two cliffs

- Negative correlation for first cliff, and positive correlation for second cliff.

- Correlation coefficient about 30% lower than for CRs seen in other flights

$$C_{Q^*W^*} = -0.19$$

# STRUCTURE FUNCTIONS & CONSTANTS

- Based on high pass filtered data
- solid black lines indicate 2/3 slope
- Structure constants for W and V are equal and much larger than those for U.

$$C_T^2 = 0.0016$$

$$C_U^2 = 0.0070 = 4.4 C_T^2$$

$$C_V^2 = C_W^2 = 0.0116 = 1.66 C_U^2$$

## BILLOW HEIGHT ESTIMATE: GRADIENT ESTIMATE

- Unlike CRs from other flights, vertical gradients are available as the AC climbs through the CR, but vertical gradients could be contaminated by horizontal changes, even though filtering was used.
- To be consistent with other cases, use gradients (both  $q$  and  $U$ ) after CRs—shaded regions in plots.
- Gradients level off in this region.

$$\frac{dq}{dz} \gg 0.0062 \text{ K/m}$$

$$S_z \gg 0.0041/\text{s}$$

## BILLOW HEIGHT AND ASPECT RATIO

|                                       | $\partial q / \partial z$<br>(K/m) | $Dq_{CLIFF}$<br>(K) | $H$<br>(m) | $L$<br>(m) | Aspect<br>Ratio |
|---------------------------------------|------------------------------------|---------------------|------------|------------|-----------------|
| Based on $L$ in <b>wind</b> direction |                                    |                     |            |            |                 |
| CR 1                                  | 0.0062                             | 1.1                 | 177        | <b>740</b> | 0.24            |
| CR 2                                  | 0.0062                             | 1.1                 | 177        | <b>630</b> | 0.28            |

- Compare height of 177 meters with climb data that show vertical extent of CRs is about 250 m
  - 30% difference is consistent with comparisons with other estimates of height for CRs for other flights (e.g., see Briefing 1 page 29)
- Aspect ratios are similar to those found for CRs for other flights.

## COMPARISON TO DNS AND OTHER CR'S: 040922 & 031122

---

- See Briefing 2 for details

## COMPARISON TO DNS: ASPECT RATIO

- Use DNS to estimate range of initial  $Ri$  for CR using range of aspect ratios
  - Results for both 031122 and 040922 are very similar to those from 020905
  - Comparison with DNS suggests initial  $Ri$  of layer:
    - Between 0.1 and 0.14 for 031122 among the lowest of all 5 CR cases.
    - Between 0.13 and 0.15 for 040922
  - High aspect ratio of 990806 seems out of place compared to others

## TURBULENCE SCALING: COMPARED TO OTHER CRS

| Case                    | 000606    | 020905    | 990806    | 040922    | 031122    |
|-------------------------|-----------|-----------|-----------|-----------|-----------|
| $S_z$ (1/s)             | 0.0318    | 0.0316    | 0.0220    | 0.00409   | 0.0123    |
| $H$ (m)                 | 304       | 515       | 1,145     | 177       | 191       |
| $U_S$ (m/s) = $S_z H$   | 9.7       | 16.3      | 25.2      | 7.2       | 2.7       |
| $Dq_{CLIFF}$ (K)        | 2.1       | 4.4       | 4.6       | 1.1       | 0.43      |

| $S_W$ (m/s)             | 0.514     | 0.807     | 1.76      | 0.376     | 0.1847    |
| $S_{q,FILT}$ (K)        | 0.175     | 0.408     | 0.609     | 0.358     | 0.0386    |
| $S_{U,FILT}/U_S$        | 0.042 (1) | 0.047 (4) | 0.066 (5) | 0.043 (3) | 0.042 (1) |
| $S_W/U_S$               | 0.053 (2) | 0.050 (1) | 0.070 (5) | 0.065 (3) | 0.069 (4) |
| $S_{q,FILT}/Dq_{CLIFF}$ | 0.082 (1) | 0.093 (3) | 0.133 (5) | 0.103 (4) | 0.089 (2) |

- Expect higher scaled rms values for “older”, more turbulent layers.
  - Numbers in parenthesis show rank from “youngest” (1) to “oldest” (5)
- Trend in all scaled rms values is same for 000606, 020905 and 990806. (000606 and 020905 are similar, while 990806 is more turbulent).
- No consistent trend for 040922 or 031122

## TURBULENCE SCALING: TRANSPORT

Turbulent diffusivity

$$n_{T,H} = \frac{-\langle w'q' \rangle}{\|Q\|/ \|z\|}$$

Turbulent viscosity

$$n_{T,M} = \frac{-\langle u'w' \rangle}{\|u\|/ \|z\|}$$

|        | $n_{T,H}$<br>m <sup>2</sup> /s | $n_{T,M}$<br>m <sup>2</sup> /s | $n_{T,M}/n_{T,H}$ | $n_{T,H}/(HS_W)$ | $n_{T,M}/(HS_W)$ |
|--------|--------------------------------|--------------------------------|-------------------|------------------|------------------|
| 000606 | 8.43                           | 5.35                           | 0.63              | 0.054            | 0.034            |
| 020905 | 26.9                           | 12.6                           | 0.47              | 0.065            | 0.030            |
| 990806 | 126                            | 60.2                           | 0.48              | 0.063            | 0.030            |
| 040922 | 3.45                           | 1.49                           | 0.46              | 0.041            | 0.019            |
| 031122 | 1.18                           | 0.30                           | 0.25              | 0.033            | 0.008            |

- Value for eddy diffusivity of heat for 040922 is close to those for the other 3 CR cases, but the value for 031122 is about 30-45% lower than the others.
- Values for eddy viscosity for 040922 are higher than the other cases (about 25%) and much lower for 031122 (50-60%)
- Generally, the comparisons for 040922 are promising, but the 031122 seem problematic.

## COMPARISON TO **SMC** DNS: LENGTH SCALE ANALYSIS

$$L_O \gg \sqrt{\frac{e}{N^3}}$$

$$e \gg (C_U^2 / 2)^{1.5}$$

$$L_E \gg \frac{S_q}{\mathbb{Q}}$$

$$L_B \gg \frac{S_w}{N}$$

| Case                                | 000606   | 020905    | 990806   | 040922    | 031122    |
|-------------------------------------|----------|-----------|----------|-----------|-----------|
| $e \text{ (m}^2\text{/s}^3\text{)}$ | 0.0029   | 0.0096    | 0.0322   | 0.000317  | 0.000105  |
| $L_E \text{ (m)}$                   | 91.4     | 164       | 285      | 43.7      | 46.6      |
| $L_O \text{ (m)}$                   | 31.8     | 50.9      | 160.4    | 10.4      | 13.3      |
| $L_B \text{ (m)}$                   | 36.1     | 52.2      | 163.6    | 32.9      | 22.0      |
| $L_O/L_E$                           | 0.35 (4) | 0.31 (3)  | 0.56 (5) | 0.24 (1)  | 0.29 (1)  |
| $L_E/H$                             | 0.30 (2) | 0.32 (1)  | 0.25 (4) | 0.25 (4)  | 0.24 (3)  |
| $L_O/H$                             | 0.11 (4) | 0.099 (3) | 0.14 (5) | 0.059 (1) | 0.069 (2) |
| $L_B/H$                             | 0.12     | 0.10      | 0.14     | 0.19      | 0.11      |

- SM & SMC DNS show that  $L_E$  decreases with time while  $L_O$  and  $L_O/L_E$  increase with time
- Numbers in parenthesis show rank from “youngest” (1) to “oldest” (5)
- Results for  $L_O$  and  $L_O/L_E$  for 031122 and 040922 indicate that they are relatively young layer similar to the 000606 and 020905 layers
- Results for  $L_E$  for 031122 and 040922 indicate that they are relatively mature layers similar to 990806.
- NOTE: Added  $L_B$  (not shown in Briefing 2)- trend is different than those for  $L_O$  and  $L_E$

## SUMMARY OF LAYER “AGE” ESTIMATE

|   | 000606     | 020905     | 990806      | 040922     | 031122     |
|---|------------|------------|-------------|------------|------------|

| <b>AVERAGE</b>  | <b>1.3</b> | <b>2.7</b> | <b>5</b>    | <b>3.3</b> | <b>2.3</b> |
| <b>OVERALL</b>  |            |            |             |            |            |
| <b>AVERAGE</b>  | <b>2.5</b> | <b>2.5</b> | <b>4.83</b> | <b>2.7</b> | <b>2.2</b> |

- Overall, layer “age” estimates suggest that all layers are nearly the same “age” except for 990806, which seems to clearly be much older.

## COMPARISON WITH **SM** & **SMC** DNS: TIME SCALE ANALYSIS

- Note that the scatter suggests that using DNS to ‘finely’ distinguish layer age from data may be difficult.
- However, very promising that values of length scale ratio are similar to those from **SM**
- **000606, 020905, 040922, 031122** are consistent with transition (60 to 140 shear times)
- **990806** consistent with later stage transition and early breakdown (120 to 200 shear times)
- This is consistent with:
  - Idea that CR should be seen as long as braids are sharp (after roll-up)
  - Turbulence in signal, indicating that transition has occurred

## PERSISTENCE OF CR PATTERN

- CR Should persist as long as there are distinct braids.
- Shaded rectangles show time over which sharp braids are seen in **SC** contour plots.
- Ranges from **SC** overlap time ranges from **SM** that correspond to calculated length scale ratios.
- This consistency between methods is strong evidence that KH are causing CR patterns.
- Also suggests initial Ri values consistent with those from aspect ratio analysis.
- **CR should persist at least 25 shear times:**
  - 000606 and 020905 – 13 min
  - 040922 – 14 min.
  - 990806 – 19 min.
  - 031122 – 30 min.

# TURBULENT RE NUMBER-CLIFF VELOCITY CHANGE

Look at correlation between turbulent Reynolds numbers (3 different definitions) and change in velocity during cliff-ramps ( $DU_{CLIFF}$ )

$$Re_w = \frac{S_w L_{DW}}{n} \quad L_{DW} = \frac{S_w^3}{e}$$

$$e = (C_U^2 / 2)^{3/2}$$

$$Re_U = \frac{S_U L_{DU}}{n}$$

$$q^2 = \frac{1}{2}(S_U^2 + S_V^2 + S_W^2)$$

- Data from 040922 case is circled, data from 031122 is marked with boxes.
- $DU_{CLIFF}$  correlates well with  $Re$  except for 040922 case.

## SUMMARY

---

- 031122 and 040922 are both weaker cliff-ramps than 000606, 020905 and 090806, but results confirmed earlier analysis of CRs from 000606, 020905 and 090806.
- Turbulence scaling and layer “age” analysis showed that all layers were similar (in terms of layer “age”, aspect ratio, and layer initial Ri) except for 090806.
  - 090806 had higher aspect ratio (flatter billows), higher initial Ri and was an “older” layer. DNS results show that these are somewhat consistent—Higher initial Ri lead to flatter billows, which have turbulence transition within the ramps, rather than near the braids, and as such have distinct cliffs (braids) longer than lower Ri number.
- 031122 exhibited some unique characteristics
  - May be a situation of a wave breaking, with the CR-KH layer forming at the peak temperatures during the wave.
  - Negative shear (measured during climbout) suggests RCs, like 000606—decreasing temperature during ramps – but temperature shows increase during ramps (CRs).
